Decidability of Bisimulation Equivalence for Normed Pushdown Processes

Colin Stirling

1 Introduction

In the classical theory of automata the expressive power of pushdown automata is matched by context-free grammars. Both accept the same family of languages, the context-free languages. Concurrency theory requires a more intensional exposition of behaviour (as language equivalence need not be preserved in the presence of communicating abstract machines). Many finer equivalences have been proposed. Bisimulation equivalence, due to Park and Milner, has received much attention.

Baeten, Bergstra and Klop proved that bisimulation equivalence is decidable for irredundant context-free grammars (without the empty production). Within process calculus theory these grammars correspond to normed BPA processes. Their proof relies on isolating a complex periodicity from the transition graphs of these processes. Simpler proofs of the result soon followed which expose algebraic structure.

Caucal and Monfort showed that normed pushdown processes (the process analogue of irredundant pushdown automata without ϵ-transitions) are strictly more expressive than normed BPA with respect to bisimulation equivalence. In this paper we prove that bisimulation equivalence is decidable for this richer family of processes. However the proof is not easy, and does not follow immediately from the techniques used for showing decidability of normed BPA. One indication of this is that the proof of decidability of bisimulation equivalence for BPP (Basic Parallel Processes) is similar to that for BPA. However, bisimulation equivalence is undecidable for the pushdown extension to BPP.

2 Normed pushdown processes

Ingredients for describing pushdown processes are a finite set of states $\mathcal{P} = \{p_1, \ldots, p_k\}$, a finite set of stack symbols $\Gamma = \{X_1, \ldots, X_m\}$, a finite set of actions $\mathcal{A} = \{a_1, \ldots, a_n\}$ and a finite family of basic transitions, each of the form $pX \xrightarrow{a} q\alpha$ where p and q are states, a is an action, X is a stack symbol and α is a sequence of stack symbols. A *pushdown process* is then any expression $p\alpha$, $p \in \mathcal{P}$ and $\alpha \in \Gamma^*$, whose behaviour (transition graph) is determined by the basic transitions together with the following prefix rule, where $\beta \in \Gamma^*$:

$$\text{if } pX \xrightarrow{a} q\alpha \text{ then } pX\beta \xrightarrow{a} q\alpha\beta$$

This account follows the presentation of Caucal [6]. It is a slight redescription of classical pushdown automata (without ϵ-transitions and final states), as for instance in [15], viewing them as generators instead of as acceptors.

Example 1 Let $\mathcal{P} = \{p, q, r, s\}$, $\Gamma = \{X\}$ and $\mathcal{A} = \{a, b, c, d\}$. The family of basic transitions is

$$\{pX \xrightarrow{a} pXX,\ pX \xrightarrow{c} q\epsilon,\ pX \xrightarrow{b} r\epsilon,\ qX \xrightarrow{d} sX,\ sX \xrightarrow{d} q\epsilon,\ rX \xrightarrow{d} r\epsilon\}$$

where ϵ is the empty stack sequence. The transition graph generated by pX is:

$$\begin{tikzcd}
q\epsilon & sX \arrow[l, "d"'] & qX \arrow[l, "d"'] & sXX \arrow[l, "d"'] & qXX \arrow[l, "d"'] & \dots \arrow[l, "d"'] \\
pX \arrow[u, "c"] \arrow[rr, "a"] \arrow[d, "b"] & & pXX \arrow[u, "c"] \arrow[rr, "a"] \arrow[d, "b"] & & pXXX \arrow[u, "c"] \arrow[r, "a"] \arrow[d, "b"] & \dots \\
r\epsilon & & rX \arrow[ll, "d"'] & & rXX \arrow[ll, "d"'] & \dots \arrow[l, "d"']
\end{tikzcd}$$

For any $n \geq 0$ the transition $qXX^n \xrightarrow{d} sXX^n$ is derived from the basic transition $qX \xrightarrow{d} sX$ using the prefix rule when β is X^n. □

Example 1 illustrates how a pushdown process may generate an infinite state transition graph. In the following we are interested in comparing the behaviour of two pushdown processes. Without loss of generality, we can assume that they are built from the same ingredients $\mathcal{P}$, Γ, $\mathcal{A}$ and basic transitions (as the appropriate disjoint union, with respect to states and stack symbols, of two pushdown descriptions is a pushdown description). One notion of behaviour of $p\alpha$ is the language it generates, which is the set of words $\{w \in \mathcal{A}^* : \exists q \in \mathcal{P}. p\alpha \xrightarrow{w} q\epsilon\}$ where the extended transitions $\xrightarrow{w}$ are defined in the usual way. Acceptance is by empty stack instead of by final state (see [15]). The process pX of Example 1 generates the language $\{a^n b d^n : n \geq 0\} \cup \{a^n c d^{2n} : n \geq 0\}$. Any language generated by a pushdown process is context-free, and for each context-free language without the empty string there is a pushdown process which generates it. This remains true under the following restriction. A process $p\alpha$ is *normed* if every reachable process with a non-empty stack generates a non-empty language. (That is, for every $q\beta$ such that $\beta \neq \epsilon$ and $p\alpha \xrightarrow{v} q\beta$ for some v, there is a w and a state r, such that $q\beta \xrightarrow{w} r\epsilon$.) Normedness amounts to irredundancy in the pushdown automaton. In the rest of the paper we assume this restriction to normed pushdown processes.

Each context-free language without the empty string is also generated by a normed pushdown process whose state set $\mathcal{P}$ contains just one state. In which case $\mathcal{P}$ is superfluous, and the result is a normed context-free or BPA process (in Greibach normal form). The stack symbols Γ are the nonterminals and basic transitions have the form $X \xrightarrow{a} \alpha$. The prefix rule is: if $X \xrightarrow{a} \alpha$ then $X\beta \xrightarrow{a} \alpha\beta$. The language generated by a context-free process α is $\{w : \alpha \xrightarrow{w} \epsilon\}$. There is a standard transformation, see [15], which translates a normed pushdown process into a normed context-free process which generates the same language. With respect to languages, the expressive power of normed context-free processes is the same as normed pushdown processes.

Concurrency theory is built on a more intensional account of behavioural equivalence than that given by languages. A pivotal notion, due to Park and Milner, is bisimilarity which is finer than language equivalence on processes.

Definition 1 A binary relation $\mathcal{R}$ between processes is a bisimulation relation provided that whenever $(E, F) \in \mathcal{R}$, for all a

$$\begin{array}{l} \text{if } E \xrightarrow{a} E' \text{ then } \exists F'.F \xrightarrow{a} F' \text{ and } (E', F') \in \mathcal{R}, \text{ and} \\ \text{if } F \xrightarrow{a} F' \text{ then } \exists E'.E \xrightarrow{a} E' \text{ and } (E', F') \in \mathcal{R}. \end{array}$$

Two processes E and F are defined to be bisimulation equivalent, or bisimilar, written $E \sim F$, if there is a bisimulation relation $\mathcal{R}$ relating them.

The transformation from pushdown processes to context-free processes does not preserve bisimulation equivalence. In fact, with respect to bisimilarity normed pushdown processes constitute a richer family than normed context-free processes, as shown by Caucal and Monfort [7]. Their proof is very elegant, and utilises the canonical graph of a process which is the quotient of its transition graph with respect to bisimulation equivalence. For instance, the canonical graph for Example 1 fuses together the pairs of vertices labelled qX^n and rX^{2n} for any $n \geq 0$. Normed context-free processes are closed under canonical graphs in the sense that for each such canonical graph there is a normed context-free process whose transition graph is isomorphic to it. Normed pushdown processes fail to have this property. Caucal and Monfort show that Example 1 is a counter-example, as its canonical graph lacks the regular structure (as identified by Muller and Schupp [19]) that the transition graph of a pushdown process must possess. Burkart and Steffen provide additional insight into pushdown processes [3], by showing that, unlike context-free processes, they are closed under Hoare parallel composition with finite state processes (with respect to bisimilarity). Moreover they demonstrate that the family of pushdown processes is the smallest extension of context-free processes with this closure property.

Baeten, Bergstra and Klop proved that bisimulation equivalence is decidable for normed context-free processes [1, 2]. Simpler proofs were developed in [5, 11, 17, 13], and [14] showed that there is even a polynomial time decision procedure. The decidability result was generalized in [10] to encompass unnormed processes, and then refined in [4] to give upper bounds. Groote and Hüttel proved that other standard equivalences on processes (traces, failures, simulation, 2/3-bisimulation etc..,) are all undecidable [12]. Similar results were proved for Basic Parallel Processes, BPP, which are like context-free processes except that a process expression α is a multiset[1]. Christensen, Hirshfeld and Moller showed that bisimulation equivalence is decidable for normed BPP [8], and this result was generalised in [9] to include the unnormed case. Hüttel proved that the other equivalences are undecidable [16].

Decidability of bisimulation equivalence for normed pushdown processes is harder to show than for normed context-free processes. There are many reasons for this. First Baeten, Bergstra and Klop's method is not applicable, as normed pushdown transition graphs need not display the periodicity upon which their proof relies. Secondly, the structural methods in the simplifed proofs of decidability, which appeal to decomposition and congruence, are not immediately applicable, as it is not clear what are the components of a pushdown process: a context-free process $X_1 \ldots X_n$ is built from the subprocesses X_i, but a process $pX_1 \ldots X_n$ does not contain X_i as a pushdown component. Perhaps the clearest indication of the increased difficulty is that for the pushdown extension of BPP[2] bisimulation equivalence is undecidable, a result due to Hirshfeld (utilizing Jančar's technique for showing undecidability of bisimilarity for Petri nets [18]).

The proof presented below of decidability of bisimulation equivalence for normed pushdown processes consists of two semi-decision procedures (for which we are unable to provide a complexity measure). One half of the proof is easy, as bisimilarity is characterizable using approximants when processes, such as pushdown processes, are image-finite[3].

Definition 2 The family $\{\sim_n : n \geq 0\}$ is defined inductively as follows

$$\begin{array}{l} E \sim_0 F \text{ for all processes } E, F \\ E \sim_{n+1} F \text{ iff for each } a \in \mathcal{A} \\ \quad \text{if } E \xrightarrow{a} E' \text{ then } \exists F'. F \xrightarrow{a} F' \text{ and } E' \sim_n F', \text{ and} \\ \quad \text{if } F \xrightarrow{a} F' \text{ then } \exists E'. E \xrightarrow{a} E' \text{ and } E' \sim_n F' \end{array}$$

The following is a standard result.

Proposition 1 *If* E *and* F *are image-finite then* $E \sim F$ *iff* $\forall n \geq 0.\ E \sim_n F$.

For each $n \geq 0$, the relation $\sim_n$ is decidable for pushdown processes, and therefore bisimulation inequivalence is semi-decidable via the simple procedure which seeks the least i such that $p\alpha \not\sim_i q\beta$. Therefore we just need to establish the semi-decidability of bisimulation equivalence. The crux of this part of the proof is that there is a finite tableau proof of $p\alpha \sim q\beta$. As finite proofs can be enumerated, this amounts to a semi-decision procedure. The method generalises the technique developed by the author and Hüttel [17]. It relies upon exposure of structure within normed pushdown processes. We introduce a finer equivalence than bisimilarity to ensure a congruence, and we show that with respect to it

[1] The prefix rule becomes: if $X \xrightarrow{a} \alpha$ then $\delta X \beta \xrightarrow{a} \delta\alpha\beta$.

[2] When the prefix rule is: if $pX \xrightarrow{a} q\alpha$ then $p\delta X\beta \xrightarrow{a} q\delta\alpha\beta$.

[3] E is image-finite if for each $w \in A^*$ the set $\{F : E \xrightarrow{w} F\}$ is finite.

pushdown processes can be taken apart, when extra stack symbols are introduced.

3 Congruence and decomposition

Two key properties underpin decidability of bisimulation equivalence on normed context-free processes:

$$\begin{array}{ll} \text{Congruence :} & \text{if } \alpha \sim \beta \text{ then } \alpha\delta \sim \beta\delta \\ \text{Decomposition :} & \text{if } \alpha\delta \sim \beta\delta \text{ then } \alpha \sim \beta \end{array}$$

Explicit use of these features can be seen in the decidability proof using tableaux [17]. In fact, there is a stronger property of unique prime decomposition due to Hirshfeld [13]. In the more general case, when the restriction to being normed is lifted, the first feature still holds but the second can fail. However bisimulation equivalence is still decidable because a weakened version of decomposition holds: if there are infinitely many different δ (up to $\sim$) such that $\alpha\delta \sim \beta\delta$ then $\alpha \sim \beta$.

Neither property holds for normed pushdown processes. A counterexample to congruence is that although $qX \sim rXX$ in Example 1 of the previous section, $qXX \not\sim rXXX$. Example 1 also furnishes instances of failure of decomposition such as $rX^6 \sim qX^3$ but $rX^5 \not\sim qX^2$.

Congruence fails because bisimilarity of pushdown processes does not imply that they agree on their final states when the stack empties: for instance the bisimulation relation between qX and rXX contains the pair $(q\epsilon, r\epsilon)$. However a congruence can be enforced by strengthening the definition of bisimulation equivalence.

Definition 1 A binary relation $\mathcal{R}$ on pushdown processes is an a-bisimulation provided that whenever $(p\alpha, q\beta) \in \mathcal{R}$, for all $a \in \mathcal{A}$

$$\begin{array}{l} \text{if } \alpha = \epsilon \text{ then } \beta = \epsilon \text{ and } p = q, \text{ and} \\ \text{if } \beta = \epsilon \text{ then } \alpha = \epsilon \text{ and } p = q, \text{ and} \\ \text{if } p\alpha \xrightarrow{a} p'\alpha' \text{ then } \exists q'\beta'.\, q\beta \xrightarrow{a} q'\beta' \text{ and } (p'\alpha', q'\beta') \in \mathcal{R}, \text{ and} \\ \text{if } q\beta \xrightarrow{a} q'\beta' \text{ then } \exists p'\alpha'.\, p\alpha \xrightarrow{a} p'\alpha' \text{ and } (p'\alpha', q'\beta') \in \mathcal{R}. \end{array}$$

The "a" stands for "agreeing", as the first two clauses require final states to be the same when processes terminate. Two pushdown processes $p\alpha$ and $q\beta$ are a-bisimilar, written $p\alpha \equiv q\beta$, if there is an a-bisimulation relating them. Note that the earlier pair qX and rXX are not a-bisimilar. Later we shall relate $\sim$ and $\equiv$.

Not surprisingly a-bisimilarity is an equivalence relation, and it is also a congruence with respect to stacking.

Proposition 1 *The relation $\equiv$ is an equivalence relation.*

Proposition 2 *If $p\alpha \equiv q\beta$ then $p\alpha\delta \equiv q\beta\delta$.*

A-bisimilarity can also be characterized using approximants.

Definition 2 The family $\{\equiv_n \colon n \geq 0\}$ is defined inductively on pushdown processes as follows:

$pX\alpha \equiv_0 qY\beta$ and $p\epsilon \equiv_0 p\epsilon$
$p\alpha \equiv_{n+1} q\beta$ iff $p\alpha \equiv_0 q\beta$, and for each $a \in \mathcal{A}$,
if $p\alpha \xrightarrow{a} p'\alpha'$ then $\exists q'\beta'. q\beta \xrightarrow{a} q'\beta'$ and $p'\alpha' \equiv_n q'\beta'$, and
if $q\beta \xrightarrow{a} q'\beta'$ then $\exists p'\alpha'. p\alpha \xrightarrow{a} p'\alpha'$ and $p'\alpha' \equiv_n q'\beta'$.

Notice that the base relation $\equiv_0$ does not include all pairs of pushdown processes.

Proposition 3 *$p\alpha \equiv q\beta$ iff $\forall n \geq 0.\ p\alpha \equiv_n q\beta$.*

We define an extended pushdown description by augmenting the stack symbols Γ with a finite family of stack constants $\mathcal{W}$. Assume that the state set of the pushdown description is $\mathcal{P} = \{p_1, \ldots, p_k\}$. Each new stack symbol $W \in \mathcal{W}$ has an associated definition

$$W \stackrel{\text{def}}{=} (q_1\delta_1, \ldots, q_k\delta_k)$$

where each $q_i \in \mathcal{P}$, and each δ_i is a sequence of stack elements, possibly including constants. However we assume that if $\delta_i \neq \epsilon$ then its first symbol belongs to Γ. The intention is that for each state $p_j \in \mathcal{P}$ the behaviour of p_jW is that of $q_j\delta_j$, the jth component of the definition of W[4]. An *extended* pushdown process is an expression $p\alpha$ where $\alpha = \epsilon$ or $\alpha \in \Gamma(\Gamma \cup \mathcal{W})^*$. Basic transitions are unaffected, remaining of the form $pX \xrightarrow{a} q\alpha$ where $X \in \Gamma$ and $\alpha \in \Gamma^*$. However the prefix rule is generalised to

$$\text{if } pX \xrightarrow{a} q\alpha \text{ then } pX\beta \xrightarrow{a} [q\alpha\beta]$$

where bracketing [ ] is defined as follows:

$$\begin{aligned} [p_i\epsilon] &= p_i\epsilon, \text{ and} \\ [p_iX\beta] &= p_iX\beta, \text{ and} \\ [p_iW\beta] &= [q_i\delta_i\beta] \text{ when } W \stackrel{\text{def}}{=} (q_1\delta_1, \ldots, q_k\delta_k) \end{aligned}$$

Therefore it follows that whenever $p\alpha$ is an extended pushdown process and $p\alpha \xrightarrow{w} q\beta$ then $q\beta$ is also an extended pushdown process.

The presence of constants does not affect congruence, and they also provide a handle for composing pushdown processes.

Proposition 4 *If $pX\alpha \equiv qY\beta$ then $pX\alpha W \equiv qY\beta W$.*

Proposition 5 *If $W \stackrel{\text{def}}{=} (q_1\delta_1\beta, \ldots, q_k\delta_k\beta)$ and $V \stackrel{\text{def}}{=} (q_1\delta_1, \ldots, q_k\delta_k)$ then $pX\alpha W \equiv pX\alpha V\beta$.*

[4] This selection notation $(\ldots)$ for pushdown processes is used in [20, 3].

Proposition 6 *If* $W \stackrel{\text{def}}{=} (q_1\delta_1,\ldots,q_k\delta_k)$ *and* $V \stackrel{\text{def}}{=} (r_1\lambda_1,\ldots,r_k\lambda_k)$ *and for each* $i : 1 \leq i \leq k$, $q_i\delta_i \equiv r_i\lambda_i$ *then* $pX\alpha W \equiv pX\alpha V$.

It is time to examine the condition of being normed more carefully. The *norm* of a process $p\alpha$, when α may contain constants, is a k-tuple $(n_1,\ldots,n_k)$ where each $n_i \in \mathbb{N} \cup \{\perp\}$. The component n_i is either the length of a shortest word w such that $p\alpha \xrightarrow{w} p_i\epsilon$ or there is no such word and n_i is the undefined element $\perp$. We let $\mathrm{n}(p\alpha)$ be the norm of $p\alpha$, and we let $\mathrm{n}(p\alpha)_i$ be its ith component. The restriction to normed processes implies that at least one entry in a norm is different from $\perp$. Let $\max(p\alpha)$ be the maximum defined entry in $\mathrm{n}(p\alpha)$ and $\min(p\alpha)$ be the least defined entry. Finally we let $\mathrm{D}(p\alpha)$ be the set $\{i : \mathrm{n}(p\alpha)_i \neq \perp\}$. We can now slightly refine the previous Proposition.

Proposition 7 *If* $W \stackrel{\text{def}}{=} (q_1\delta_1,\ldots,q_k\delta_k)$ *and* $V \stackrel{\text{def}}{=} (r_1\lambda_1,\ldots,r_k\lambda_k)$ *and for each* $i \in \mathrm{D}(pX\alpha)$. $q_i\delta_i \equiv r_i\lambda_i$ *then* $pX\alpha W \equiv pX\alpha V$.

We now define two useful measures on a pushdown description. We let M be just greater than the maximum norm of a stack symbol in Γ:

$$M \stackrel{\text{def}}{=} 1 + \max\{\max(pX) \ : \ p \in \mathcal{P} \text{ and } X \in \Gamma\}$$

And we let G be the maximum length of a stack sequence in a basic transition, where $|\ |$ means "length of":

$$G \stackrel{\text{def}}{=} \max\{|\alpha| \ : \ pX \xrightarrow{a} q\alpha \text{ is a basic transition}\}$$

The family of finite constants $\mathcal{W}$ is partitioned into two. First are *simple* constants. Each has a definition $U \stackrel{\text{def}}{=} (q_1\delta_1,\ldots,q_k\delta_k)$ where each $\delta_i \in \Gamma^+$ and $|\delta_i| \leq MG$: constants are not allowed in their definition, and neither is the empty stack. Up to renaming of constants, there are only finitely many different simple constants, because of the constraint on their length. Their role is to provide a format for decomposition, as the next result shows.

Lemma 1 *If* $pX\alpha \equiv q\beta\delta$ *and* $\beta \in \Gamma^+$ *and* $\max(pX) < \min(q\beta)$ *and* $|\beta| \leq M$ *then there is a simple* $U \stackrel{\text{def}}{=} (q_1\gamma_1,\ldots,q_k\gamma_k)$ *such that*

1. $pXU\delta \equiv q\beta\delta$, *and* 2. $\forall i \in \mathrm{D}(pX). [p_i\alpha] \equiv q_i\gamma_i\delta$.

Proof: Suppose $pX\alpha \equiv q\beta\delta$ and $\beta \in \Gamma^+$ and $\max(pX) < \min(q\beta)$ and $|\beta| \leq M$. For each $i \in \mathrm{D}(pX)$ consider a shortest w_i such that $pX \xrightarrow{w_i} p_i\epsilon$. Therefore, $pX\alpha \xrightarrow{w_i} [p_i\alpha]$. Since $pX\alpha \equiv q\beta\delta$ we know that $q\beta\delta \xrightarrow{w_i} q_i\lambda_i$ and $[p_i\alpha] \equiv q_i\lambda_i$. However, as $\max(pX) < \min(q\beta)$ it follows that $\lambda_i = \gamma_i\delta$ and $q\beta \xrightarrow{w_i} q_i\gamma_i$ and $\gamma_i \neq \epsilon$, and as $\beta \in \Gamma^+$ this means that $\gamma_i \in \Gamma^+$. Also because $|w_i| < M$ (and $|\beta| \leq M$) it follows that $|\gamma_i| \leq MG$. Let $U \stackrel{\text{def}}{=} (q_1\gamma_1,\ldots,q_k\gamma_k)$ where for each $i \in \mathrm{D}(pX)$ $q_i\gamma_i$ is determined as above and for each $i \notin \mathrm{D}(pX)$, $q_i\gamma_i = pX$. By definition U is a simple constant, and by construction 2 holds. By induction on n it follows that for any $p'\alpha'$ such that $\alpha' \in \Gamma^+$ and $\mathrm{D}(p'\alpha') \subseteq \mathrm{D}(pX)$, $p'\alpha'U\delta \equiv_n p'\alpha'\alpha$. Therefore $pXU\delta \equiv pX\alpha$, which implies 1. □

The other constants are *recursive*. Each recursive constant has a definition $V \overset{\text{def}}{=} (q_1\lambda_1, \ldots, q_k\lambda_k)$, where each λ_i is either empty or of the form $\lambda_i'V$ where V is the defining constant and λ_i' is a non-empty sequence of stack symbols which may contain simple (but not recursive) constants. The first use of these constants is to relate $\sim$ and $\equiv$. Let I be a special initial constant $I \overset{\text{def}}{=} (p_1\epsilon, \ldots, p_1\epsilon)$.

Proposition 8 *$pX\alpha \sim qY\beta$ iff $pX\alpha I \equiv qY\beta I$.*

The starting point is to show that $p\alpha \sim q\beta$ is semi-decidable, and when α and β are both non-empty the problem reduces to $p\alpha I \equiv q\beta I$. When α and β are sufficiently large, Lemma 1 provides a mechanism for further reduction, to an equivalence of the form $pXU\delta \equiv q\beta'\delta$, where there is the common subsequence δ. Simple decomposition, if $p\alpha\delta \equiv q\beta\delta$ then $p\alpha \equiv q\beta$, does not hold in general. However there is a weakened version, which is a little subtle, and should be compared with the general case of context-free processes, as described earlier. This is the second and chief role of recursive constants. We now state the central result, which oils the decidability proof. In it we assume that $\Delta \subseteq (\Gamma \cup \mathcal{W})^*$ is a finite or infinite set of stack sequences.

Lemma 2 *If $pX\alpha\delta \equiv qY\beta\delta$ for all $\delta \in \Delta$, and α and β do not contain recursive constants then there exists a finite family $\mathcal{V}$ of recursive constants such that for each $\delta \in \Delta$ there is a $V \overset{\text{def}}{=} (q_1\lambda_1, \ldots, q_k\lambda_k)$ in $\mathcal{V}$ such that*

1. $pX\alpha V \equiv qY\beta V$,
2. $\forall i \in \mathrm{D}(pX\alpha) \cup \mathrm{D}(qY\beta)$. *if* $\lambda_i = \epsilon$ *then* $[p_i\delta] \equiv [q_i\delta]$,
3. $\forall i$. *if* $\lambda_i = \lambda_i'V$ *then* $[p_i\delta] \equiv q_i\lambda_i'\delta$.

Proof: Suppose $pX\alpha\delta \equiv qY\beta\delta$ for all $\delta \in \Delta$, and α, β do not contain recursive constants. Assume a total ordering on the state set $\{p_1, \ldots, p_k\}$, so that $p_i < p_j$ whenever $i < j$. We say that the recursive constant V is definitionally equivalent to V' if their definitions are the same except for their occurrences of V and V': in which case, for all $n \geq 0$, $pX\alpha V \equiv_n pX\alpha V'$ for any p, X and α.

For each $\delta \in \Delta$ we define the family $\{V_i^\delta : 0 \leq i \leq k^2\}$ iteratively, so that for each i properties 2 and 3 hold for V_i^δ and property 1 holds when $i = k^2$. Furthermore, for each i the set $\{V_i^\delta : \delta \in \Delta\}$ when quotiented by definitional equivalence is finite. From this the result follows by taking $\mathcal{V}$ to be the family $\{V_{k^2}^\delta : \delta \in \Delta\}$ after quotienting by definitional equivalence.

The element $V_0^\delta \overset{\text{def}}{=} (p_1\epsilon, \ldots p_k\epsilon)$. Clearly, both 2 and 3 hold, and the set $\{V_0^\delta : \delta \in \Delta\}$ is a singleton up to definitional equivalence. Assume V_i^δ for $0 \leq i < k^2$ has been defined, and that both 2 and 3 hold for it, and that the set $\{V_i^\delta : \delta \in \Delta\}$ is finite up to definitional equivalence. If property 1 is also true then let V_j^δ, for all $j : i \leq j \leq k^2$ be V_i^δ. Otherwise V_{i+1}^δ is constructed as a refinement of V_i^δ.

As 1 fails there is a least $n \geq 0$ such that $pX\alpha V_i^\delta \not\equiv_n qY\beta V_i^\delta$. By definition $n > 0$. However, we also know that $pX\alpha\delta \equiv qY\beta\delta$. Hence $pX\alpha \xrightarrow{a} [p_1'\alpha_1]$ and $qY\beta \xrightarrow{a} [q_1\beta_1]$ for some a and $p_1'\alpha_1$ and $q_1\beta_1$ such that $[p_1'\alpha_1\delta] \equiv [q_1\beta_1\delta]$ and $[p_1'\alpha_1 V_i^\delta] \not\equiv_{n-1} [q_1\beta_1 V_i^\delta]$. The sequences α_1 and β_1 do not contain recursive constants. If both α_1 and β_1 are non-empty then we can obtain a subsequent pair $p_2'\alpha_2$ and $q_2\beta_2$ such that $[p_2'\alpha_2\delta] \equiv [q_2\beta_2\delta]$ and $[p_2'\alpha_2 V_i^\delta] \not\equiv_{n-2} [q_2\beta_2 V_i^\delta]$, and so on. Therefore as n is finite we must reach a pair $p_j'\alpha_j$ and $q_j\beta_j$ such that $[p_j'\alpha_j\delta] \equiv [q_j\beta_j\delta]$ and $[p_j'\alpha_j V_i^\delta] \not\equiv_{n-j} [q_j\beta_j V_i^\delta]$, where α_j or β_j is empty (and neither contain recursive constants).

Without loss of generality assume that $\alpha_j = \epsilon$. Let $r\lambda$ be the entry for p_j' in V_i^δ. There are two cases.

Case 1 $\lambda = \epsilon$. Now consider β_j. First assume that $\beta_j \neq \epsilon$. Let V_{i+1}^δ be V_i^δ except that $q_j\beta_j V_{i+1}^\delta$ is associated with the state p_j' instead of $r\epsilon$ (and throughout the other entries V_{i+1}^δ replaces V_i^δ). Clearly properties 2 and 3 hold for V_{i+1}^δ given that they hold for V_i^δ. Next assume instead that $\beta_j = \epsilon$. Assume that $s\gamma$ is q_j's entry in V_i^δ. There are two subcases. First, $\gamma \neq \epsilon$. Then V_{i+1}^δ is V_i^δ except that $s\gamma$ is associated with p_j' (and throughout all entries V_{i+1}^δ replaces V_i^δ). Second, $\gamma = \epsilon$. If $p_j' < q_j$ in the total order on states V_{i+1}^δ is V_i^δ except that $r\epsilon$ is associated with q_j instead of $s\epsilon$, and if $q_j < p_j'$ then V_{i+1}^δ is V_i^δ except that $s\epsilon$ is associated with p_j' (and in both cases throughout the other entries V_{i+1}^δ replaces V_i^δ). Again clearly properties 2 and 3 both hold for V_{i+1}^δ.

Case 2 $\lambda \neq \epsilon$, and so $\lambda = \lambda' V_i^\delta$. Again consider β_j. If $\beta_j \neq \epsilon$ then as $[p_j'\delta] \equiv q_j\beta_j\delta$ by 3 we know that $[p_j'\delta] \equiv r\lambda'\delta$, and so $r\lambda'\delta \equiv q_j\beta_j\delta$. However $r\lambda' V_i^\delta \not\equiv_{n-j} q_j\beta_j V_i^\delta$ (as $[p_j'\alpha_j V_i^\delta] = r\lambda' V_i^\delta$). Therefore the proof proceeds as before by defining further pairs $r_m\lambda_m'$ and $q_{j+m}\beta_{j+m}$ such that $[r_m\lambda_m'\delta] \equiv [q_{j+m}\beta_{j+m}\delta]$ and $[r_m\lambda_m' V_i^\delta] \not\equiv_{n-(j+m)} [q_{j+m}\beta_{j+m} V_i^\delta]$. Otherwise $\beta_j = \epsilon$. Let $s\gamma$ be the entry for q_j in V_i^δ. If $\gamma = \epsilon$ then we proceed as in case 1 above (with the α and β roles reversed). If $\gamma \neq \epsilon$ then $\gamma = \gamma' V_i^\delta$ where γ' does not contain recursive constants. By 3 for V_i^δ $[q_j\delta] \equiv s\gamma'\delta$ and $[p_j'\delta] \equiv r\lambda'\delta$ and therefore $r\lambda'\delta \equiv s\gamma'\delta$, and also $r\lambda' V_i^\delta \not\equiv_{n-j} s\gamma' V_i^\delta$. Therefore again we define further pairs $r_m\lambda_m'$ and $s_m\gamma_m'$ such that $[r_m\lambda_m'\delta] \equiv [s_m\gamma_m'\delta]$, and $[r_m\lambda_m' V_i^\delta] \not\equiv_{n-(j+m)} [s_m\gamma_m' V_i^\delta]$. As n is finite there can only be finitely many invocations of 3 before V_i^δ is updated according to the first case.

The construction of V_{i+1}^δ updates exactly one entry in V_i^δ which must be of the form $r\epsilon$. The update becomes either non-empty or is replaced by an empty entry from an earlier state in the total order. For each V_i^δ the number of possible different recursive constants V_{i+1}^δ by this construction given that $pX\alpha V_i^\delta \not\equiv_n qY\beta V_i^\delta$ (with n least) is finite. Consequently the set $\{V_{i+1}^\delta : \delta \in \Delta\}$ is finite up to definitional equivalence. Moreover given the regime for updating, there can be at most k^2 updates, and therefore $pX\alpha V_{k^2}^\delta \equiv qY\beta V_{k^2}^\delta$. □

Lemma 1 allows us to reduce an equivalence of the form $pX\alpha \equiv q\beta\delta$ to $pXU\delta \equiv q\beta\delta$. In turn Lemma 2 allows us to reduce $pXU\delta \equiv q\beta\delta$ to $pXUV \equiv q\beta V$ and a family of pairs $[p_i\lambda_i'\delta] \equiv [p_i\delta]$ which have a common suffix. The next result, which is an important corollary of the previous two lemmas, generalises the reduction of $pX\alpha \equiv q\beta\delta$ to the situation $pX\alpha\delta \equiv q\beta\delta$ where there is the common suffix δ. Again we assume that Δ is a finite or infinite family of stack sequences.

Lemma 3 *If $pX\alpha_i\delta_i \equiv q\beta\delta_i$ for all $\alpha_i\delta_i \in \Delta$, and $\beta \in \Gamma^+$ and each α_i does not contain recursive constants, and $\max(pX) < \min(q\beta)$, and $|\beta| \leq M$ then there exists a finite family $\mathcal{U}$ of simple constants and a finite family $\mathcal{V}$ of recursive constants such that for each $\alpha_i\delta_i \in \Delta$ there is a $U \overset{\text{def}}{=} (r_1\gamma_1, \ldots, r_k\gamma_k)$ in $\mathcal{U}$ and a $V \overset{\text{def}}{=} (q_1\lambda_1, \ldots, q_k\lambda_k)$ in $\mathcal{V}$ such that*

1. *$pXUV \equiv q\beta V$, and*
2. *$\forall j \in \mathrm{D}(pX). [p_j\alpha_i V] \equiv r_j\gamma_j V$, and*
3. *$\forall j \in \mathrm{D}(pX\alpha_i) \cup \mathrm{D}(q\beta)$. if $\lambda_j = \epsilon$ then $[p_j\delta_i] \equiv [q_j\delta_i]$, and*
4. *$\forall j$. if $\lambda_j = \lambda'_j V$ then $[p_j\delta_i] \equiv q_j\lambda'_j\delta_i$.*

Proof: Suppose $pX\alpha_i\delta_i \equiv q\beta\delta_i$ for all $\alpha_i\delta_i \in \Delta$ and $\beta \in \Gamma^+$ and each α_i does not contain recursive constants, and $\max(pX) < \min(q\beta)$ and $|\beta| \leq M$. By Lemma 1 for each $\alpha_i\delta_i$ there is a simple $U \overset{\text{def}}{=} (r_1\gamma_1, \ldots, r_k\gamma_k)$ such that $pXU\delta_i \equiv q\beta\delta_i$ and $\forall j \in \mathrm{D}(pX)$. $[p_j\alpha_i\delta_i] \equiv r_j\gamma_j\delta_i$. By the construction in Lemma 1 we know that there are only finitely many such U (as each component of their definition is drawn from the set $\{q'\gamma' : q\beta \xrightarrow{w} q'\gamma'$ for $|w| \leq \max(pX)\}$). Let $U_1, \ldots, U_l$ be the different simple constants. We partition Δ into sets $\Delta_1, \ldots, \Delta_l$ such that for each $\alpha_i\delta_i \in \Delta_t$, with $U_t \overset{\text{def}}{=} (r_1\gamma_1, \ldots, r_k\gamma_k)$, $pXU_t\delta_i \equiv q\beta\delta_i$ and $\forall j \in \mathrm{D}(pX)$. $[p_j\alpha_i\delta_i] \equiv r_j\gamma_j\delta_i$. By Lemma 2 for each Δ_t there are finitely many recursive V such that $pXU_tV \equiv q\beta V$ and for each $\alpha_i\delta_i \in \Delta_t$ one of these recursive constants $V \overset{\text{def}}{=} (q_1\lambda_1, \ldots, q_k\lambda_k)$ has the property that $[p_j\delta_i] \equiv [q_j\lambda'_j\delta_i]$ for all $j \in \mathrm{D}(q\beta) \cup \mathrm{D}(pXU_t)$ (where if $\lambda_j = \delta V$ then $\lambda'_j = \delta$ and if $\lambda_j = \epsilon$ then $\lambda'_j = \epsilon$). Let $\mathcal{V}_t$ be this finite family of recursive constants. The proof is finished if for each $\alpha_i\delta_i \in \Delta_t$ there is a $V \in \mathcal{V}_t$ such that for all $j \in \mathrm{D}(pX)$. $[p_j\alpha_i V] \equiv q_j\gamma_j V$. Using a similar proof method to that in Lemma 2 we refine this set of recursive constants so that it becomes true. Let $\mathcal{V}_{t0}$ be $\mathcal{V}_t$. Take the least n such that there is an $\alpha_i\delta_i \in \Delta_t$ and $V \overset{\text{def}}{=} (q_1\lambda_1, \ldots, q_k\lambda_k) \in \mathcal{V}_{t0}$ with $[p_j\delta_i] \equiv [q_j\lambda'_j\delta_i]$ for all $j \in \mathrm{D}(q\beta) \cup \mathrm{D}(pX\alpha_i)$ such that $[p_j\alpha_i V] \not\equiv_n q_j\gamma_j V$. However we know that $[p_j\alpha_i\delta_i] \equiv q_j\gamma_j\delta_i$. Therefore, by the technique in the proof of Lemma 2 this means that for some j, $[p_jV] \not\equiv_0 [q'\lambda V]$ and $[p_j\delta_i] \equiv [q'\lambda\delta_i]$ and the jth component of V, $q_j\lambda_j$, has the form $r\epsilon$. We now update V. There are two cases. First if $\lambda \neq \epsilon$ then each entry $r\epsilon$ in V is replaced with $q'\lambda V$. If $\lambda = \epsilon$ then replace each entry $r\epsilon$ with the entry for q' (which cannot be $r\epsilon$). All other entries in V remain untouched. Call the resulting constant V'. A small exercise shows that for any α and β if $[p\alpha V] \equiv [q\beta V]$ then $[p\alpha V'] \equiv [q\beta V']$ (and so, in particular, $pXU_tV' \equiv q\beta V'$): this is the reason why all entries $r\epsilon$ are updated at once. Let $\mathcal{V}_{t1}$ be $\mathcal{V}_{t0}$ with V replaced by V'. Now keep repeating the procedure.

As with the argument in Lemma 2 the number of possible updates must be finite (here less than rk^2 where r is the number of constants in $\mathcal{V}_{t0}$). □

As we shall see decidability follows from the use of Lemmas 1 and 2 (and their corollary Lemma 3) in tandem.

4 Tableaux

Given a pushdown description and two normed processes $p\alpha$ and $q\beta$, the aim is to show semi-decidability of $p\alpha \sim q\beta$. If $\alpha = \epsilon$ or $\beta = \epsilon$ then checking for decidability is clear. Otherwise the problem reduces to decidability of $p\alpha I \equiv q\beta I$ where I is the initial recursive constant. Therefore, we need to extend the pushdown description with a finite family of stack constants $\mathcal{W}$. As we saw in the previous section we can include all potential simple constants. For the recursive constants we have no such upper bound (and hence the reason for semi-decidability). However, besides the initial constant I, we only need to introduce a finite family (see Lemmas 2 and 3 of the previous section) for pairs pX and $q\beta$, $\beta \in \Gamma^+$, and $|\beta| \leq M$, and for which there is a δ and an α such that $pX\alpha \equiv q\beta\delta$ or $pX\alpha\delta \equiv q\beta\delta$. Therefore we just guess the recursive constants.

We complete the decidability result by presenting a tableau proof system for a-bisimilarity. The proof system is goal directed, and consists of a finite set of rules each of the form

$$\frac{\text{Goal}}{\text{Subgoal}_1 \ \ldots\ \text{Subgoal}_n}\ C$$

where Goal is what currently is to be proved and the subgoals are what it reduces to, and C is a possible side condition on the rule application. Each goal and subgoal has the form $p\alpha = q\beta$ (the proof analogue of $p\alpha \equiv q\beta$) where the constituents are extended normed pushdown processes. Each rule is backwards sound: if all the subgoals are true then so is the goal. As we are dealing with infinite state systems there is also the important notion of when a current goal counts as terminal, for the rules only apply to nonterminals. Terminal goals are classified as either successful or unsuccessful. A *tableau proof* for Goal is a finite proof tree, whose root is Goal and all of whose leaves are successful terminals, and all of whose inner subgoals are the result of an application of one of the rules to the goal immediately above them. If the successful terminals are true it follows that the root goal is also true. We show that $pX\alpha \sim qY\beta$ iff there is a tableau proof for $pX\alpha I = qY\beta I$.

The tableau proof rules are presented in Figure 1. There are two DEC (for "decomposition") rules which introduce simple and recursive constants: their formulation directly reflects the important Lemmas of the previous section. The third rule is UNF, for "unfold": for each transition from $pX\alpha$ there is a corresponding transition from $qY\beta$, and the resulting pairs become subgoals (and vice-versa). A tableau is built from proof steps, possibly interspersed with applications of UNF. A proof step has the form

$$\text{DEC1}\ \frac{pX\alpha\delta = q\beta\delta}{[p_{i1}\alpha V] = r_{i1}\gamma_{i1}V \ldots\ [p_{il}\alpha V] = r_{il}\gamma_{il}V \quad \Lambda \quad pXUV = q\beta V}\ C1$$

Condition C1:

1. $\beta \in \Gamma^+$ and $|\beta| \leq M$ and $\max(pX) < \min(q\beta)$ and $|\delta| > 1$, and
2. $U \overset{\text{def}}{=} (r_1\gamma_1, \ldots, r_k\gamma_k)$ is simple, and $\mathrm{D}(pX) = \{i1, \ldots, il\}$, and
3. $V \overset{\text{def}}{=} (q_1\lambda_1, \ldots q_k\lambda_k)$ is recursive, and
4. $\mathrm{D}(q\beta) \cup \mathrm{D}(pX\alpha) = \{i1, \ldots, it\}$, and
5. Λ is $[q_{i1}\lambda'_{i1}\delta] = [p_{i1}\delta] \ldots [q_{it}\lambda'_{it}\delta] = [p_{it}\delta]$, where
6. if $\lambda_{ij} = \epsilon$ then $\lambda'_{ij} = \epsilon$, and if $\lambda_{ij} = \lambda''V$ then $\lambda'_{ij} = \lambda''$.

$$\text{DEC2}\ \frac{pX\alpha = q\beta\delta}{[p_{i1}\alpha] = r_{i1}\gamma_{i1}\delta \ldots\ [p_{il}\alpha] = r_{il}\gamma_{il}\delta \quad \Lambda \quad pXUV = q\beta V}\ C2$$

Condition C2:

1. $\beta \in \Gamma^+$ and $|\beta| \leq M$ and $\max(pX) < \min(q\beta)$ and $|\delta| > 1$, and
2. $U \overset{\text{def}}{=} (r_1\gamma_1, \ldots, r_k\gamma_k)$ is simple, and $\mathrm{D}(pX) = \{i1, \ldots, il\}$, and
3. $V \overset{\text{def}}{=} (q_1\lambda_1, \ldots q_k\lambda_k)$ is recursive, and
4. $\mathrm{D}(q\beta) = \{i1, \ldots, it\}$, and
5. Λ is $[q_{i1}\lambda'_{i1}\delta] = [p_{i1}\delta] \ldots [q_{it}\lambda'_{it}\delta] = [p_{it}\delta]$, where
6. if $\lambda_{ij} = \epsilon$ then $\lambda'_{ij} = \epsilon$, and if $\lambda_{ij} = \lambda''V$ then $\lambda'_{ij} = \lambda''$.

$$\text{UNF}\ \frac{pX\alpha = qY\beta}{p_1\alpha_1 = q_1\beta_1 \quad \ldots \quad p_l\alpha_l = q_l\beta_l}\ C3$$

Condition C3: For any a

1. if $pX\alpha \xrightarrow{a} p'\alpha'$ then $\exists i : 1 \leq i \leq l.\ p'\alpha' = p_i\alpha_i$ and $qY\beta \xrightarrow{a} q_i\beta_i$,
2. if $qY\beta \xrightarrow{a} q'\beta'$ then $\exists i : 1 \leq i \leq l.\ q'\beta' = q_i\beta_i$ and $pX\alpha \xrightarrow{a} p_i\alpha_i$.

Fig. 1. Tableau rules

$$\frac{pX\alpha\delta = q\beta\delta}{\ldots[p_i\alpha V] = r_i\gamma_i V \ldots \quad \ldots[q_i\lambda'_i\delta] = [p_i\delta]\ldots \quad \dfrac{pXUV = q\beta V}{\ldots}\ \text{UNF}}\ \text{DEC1}$$

or when DEC1 is not applicable, it has the form

$$\frac{pX\alpha = q\beta\delta}{\ldots[p_i\alpha] = r_i\gamma_i\delta \ldots \quad \ldots[q_i\lambda'_i\delta] = [p_i\delta]\ldots \quad \dfrac{pXUV = q\beta V}{\ldots}\ \text{UNF}}\ \text{DEC2}$$

The idea is to repeat proof steps whose roots are themselves leaves of a proof step except when the side conditions for DEC1 and DEC2 do not apply in which case the UNF rule is applied instead. DEC1 takes priority over DEC2, and DEC2 takes priority over UNF. Note that a recursive constant may only appear as a final stack symbol, and that simple constants are only explicitly introduced into processes on the left side of $=$: they can appear on the right hand side of $=$ through the presence of recursive constants, when a process becomes $[q_i V]$.

The conditions for being a terminal node are described in Figure 2. A node

Successful terminals

1. $p\alpha = p\alpha$
2. $p\alpha = q\beta$ and in the proof tree the same equation $p\alpha = q\beta$ occurs above on the path to the root.

Unsuccessful terminals

1. $p\epsilon = q\epsilon$ and $p \neq q$
2. $p\alpha = q\beta$ and $\min(p\alpha) \neq \min(q\beta)$
3. $p\alpha = q\beta$ and $p\alpha \xrightarrow{a}$ but not$(q\beta \xrightarrow{a})$
4. $p\alpha = q\beta$ and $q\beta \xrightarrow{a}$ but not$(p\alpha \xrightarrow{a})$

Fig. 2. Terminal nodes

labelled $p\alpha = q\beta$ in a proof tree is a successful terminal if it is an identity ($q\beta$ is $p\alpha$) or a repeat: that is, there is a node above it on the path to the root also labelled $p\alpha = q\beta$. In the conditions for being an unsuccessful terminal we use the standard notation $r\lambda \xrightarrow{a}$ as an abbreviation for $\exists r'\lambda'. r\lambda \xrightarrow{a} r'\lambda'$. Clearly, if a node labelled $p\alpha = q\beta$ is an unsuccessful terminal then $p\alpha \not\equiv q\beta$.

The tableau proof rules are backwards sound with respect to the approximants $\equiv_n$, and this fact is used in the following soundness result.

Lemma 1 *If there is a tableau proof for $p\alpha = q\beta$ then $p\alpha \equiv q\beta$.*

Now the main result which shows completeness of the tableau method.

Theorem 1 *$pX\alpha \sim qY\beta$ iff there is a tableau proof for $pX\alpha I = qY\beta I$.*

Proof: One half follows by Lemma 1 above and Proposition 8 of the previous section: if there is a tableau proof for $pX\alpha I = qY\beta I$ then $pX\alpha \sim qY\beta$. For the other half suppose $pX\alpha \sim qY\beta$. By Proposition 8 $pX\alpha I \equiv qY\beta I$. We now construct a tableau proof for $pX\alpha I = qY\beta I$. First we introduce all the appropriate constants. For each pX and $q\beta$, $\beta \in \Gamma^+$, $|\beta| \leq M$ and where $\max(pX) < \min(q\beta)$, we define finite sets of constants as determined by Lemmas 1, 2 and 3 of the previous section. Now we repeatedly build proof steps that preserve truth until we reach terminals. Lemma 3 of the previous section and the introduction of constants guarantee that if $pX\alpha\delta = q\beta\delta$ is a subgoal with $\beta \in \Gamma^+$ and $|\beta| \leq M$ and $\max(pX) < \min(q\beta)$ and $|\delta| > 1$ then DEC1 is applicable. If this rule is not applicable to $pX\alpha = q\beta\delta$ and $\beta \in \Gamma^+$ and $|\beta| \leq M$ and $\max(pX) < \min(q\beta)$ and $|\delta| > 1$ then DEC2 is applicable by Lemmas 2 and 1 of the previous section, and the introduction of constants. Otherwise the rule UNF is always applicable to a nonterminal subgoal (as any process in a tableau has the form $pX\alpha$ or $p\epsilon$). Clearly, as truth is preserved it is not possible to reach an unsuccessful terminal goal.

The only impediment is the possibility that the proof construction never ends, that we build a proof tree with an infinite path. The rest of the proof shows that this is impossible. Note that because of normedness, for each $k \geq 1$ the set $\{r\delta$: for some $p\alpha$ such that $|\alpha| < k$, $r\delta \equiv p\alpha$ and δ and α contain at most one recursive constant$\}$ is finite.

Let S be the following measure

$$\max(\{|\lambda_i| + M \,:\, V \overset{\mathrm{def}}{=} (q_1\lambda_1, \ldots, q_k\lambda_k) \text{ is recursive}\} \cup \{MG + 2\} \cup \{4\})$$

In a goal $p\alpha = q\beta$ we say that $p\alpha$ is a left process and $q\beta$ is a right process. Note the following observations:

1. Any occurrence of a left or right process has at most one recursive constant which can only appear as the final stack symbol.

2. The only way that simple constants can be introduced into a right process is through the UNF rule, in the circumstance that $pX\alpha = qYV$ and $qY \xrightarrow{a} r\epsilon$: this means that in a right process $q\beta U\delta$ where U is simple, $|U\delta| < S$.

3. The only circumstance that DEC1 and DEC2 is not applicable to a nonterminal goal $pX\alpha = q\beta\delta$, $|\beta| \in \Gamma^+$, is when $\max(pX) \not< \min(q\beta)$ and $\delta = \epsilon$ or $\delta = V$ or $\delta = U\delta_1$ and U is simple. In which case $|\beta\delta| < S$.

Suppose $p_1\alpha_1 = q_1\beta_1, \ldots, p_n\alpha_n = q_n\beta_n, \ldots$ is an infinite path of distinct goals in the tableau (with $p_1\alpha_1 = pX\alpha I$ and $q_1\beta_1 = qY\beta I$). Let g_i be the ith goal in this sequence. We show that there must be a repeat goal in this sequence: for some i goal g_i is a terminal. A little notation. Consider the rule that takes g_i to g_{i+1}: if the rule is UNF we say g_{i+1} is an UNF successor of g_i, if the rule is DEC1 or DEC2 then we say it is an l-successor if it is of the form $p_i\alpha V = r_i\gamma_i V$ or $p_i\alpha = r_i\gamma_i\delta$, or an m-successor if it is of the form $[q_i\lambda'_i\delta] = [p_i\delta]$ or an r-successor if it has the form $pXUV = q\beta V$.

The following are true for the sequence $g_1, \ldots, g_n, \ldots$

1. There is an i such that for all $j \geq i$. g_j is not an r-successor from either DEC1 or DEC2 (because the left process of such a goal has the form $pXUV$ and $|XUV| < S$).

2. There is an i such that for all $j \geq i$. g_j is not an l-successor from DEC1 (because the right process of such a goal has the form $r_i\gamma_i V$ and $|\gamma_i V| < S$).

3. There is an i such that for all $j \geq i$. g_j is not an UNF successor. First by 1 above there is an i such that no later goal is an UNF successor via r-successors of DEC1 or DEC2, and by observation 3 earlier DEC1 and DEC2 are not applicable to a goal only when its right process $q\beta$ is such that $|\beta| < S$.

Hence there is a suffix $g_i, \ldots, g_n, \ldots$ of goals such that each goal is an m-successor from DEC1 or DEC2, or an l-successor from DEC2. Clearly, there cannot be $j \geq i$ such that for all $k \geq j$ g_k is an m-successor from DEC1 as each application reduces the right process by at least one stack symbol except when a simple constant is encountered: in which case the stack may temporarily expand but the number of simple constants is reduced by one. (Notice that a recursive constant cannot be "exposed" as an m-successor from either DEC1 or DEC2 because of the side condition $|\delta| > 1$.) Moreover, there must be an i such that for all $j \geq i$ g_j is not an m-successor from DEC1. Consider any sequence $g_i, \ldots, g_{i+k}$ of goals which are m-successors from DEC1 and such that DEC1 is not applicable to g_{i+k}. So g_{i+k-1} has the form $pX\alpha\delta = q\beta\delta$ and g_{i+k} has the form $[q_i\lambda_i'\delta] = [p_i\delta]$: either δ is small (of length less than $M + 2$) or δ has the form $\beta_1 U \delta_1$ where U is simple (and $|\beta_1| \leq M$). Hence either $|\beta\delta| < S$ or the right process of g_{i+k} has size less than S. Therefore there is a suffix $g_i, \ldots, g_n, \ldots$ such that each goal is an m-successor from DEC2 or an l-successor from DEC2. However if DEC1 is not applicable to an m-successor from DEC2 then, by reasoning similar to above, either its right process or the right process in the preceeding goal has size less than S. Thus, for some $j \geq i$ for all $k \geq j$ every goal is an l-successor from DEC2. This is impossible. Each application reduces the left process by at least one stack symbol except when a simple constant or a recursive constant is encountered: in the first case the stack may temporarily expand but the number of simple constants is reduced by one and in the second case, whenever a recursive constant is exposed, the left process has size less than S. □

5 Conclusion

We have shown that bisimulation equivalence is decidable for normed pushdown processes. However, no complexity measure is available as the decision procedure essentially relies on Lemmas 2 and 3 of Section 3. Moreover, it is not clear if the proof can be generalised to include unnormed pushdown processes: the main problem is that we are then unable to show completeness of the tableau proof system.

Another area for further work is the long standing issue of decidability of language equivalence for DPDA. The result proved in this paper generalises [20]. However the proof method is very different: [20] uses Valiant's parallel stacking technique whereas the method here relies on congruence and decomposition. Further work is needed to establish whether we can offer new insight into this difficult open problem.
